

One of our biggest challenges was find a dataset that matched with our initial use-of-force dataset. Fortunately, our unauthorized encampments had a precinct field that matched with our dataset and allowed us to join on that field.

Another challenge we faced was that we did not originally include precinct since it was not determined to be a critical field for last week, and we did not know that our new dataset was going to need to merge on precinct. We resolved this by adding a column to our cleaned dataset from week 6 with the respective precinct values from our cleaned data set.

For our derived column, we converted both reporting community area and zip code to string types so we could concatenate the two columns.

For our NaN values, we ultimately decided to drop our NaN values since the data on zip codes and recording information around encampments was missing outright and could not be imputed or inferred. Additionally, we picked the essential columns of location, zip code, precinct, reporting area,
